

ARCHITETTURE DATI

Progetto MongoDB

Relazione di: Riccardo Andena 859643
Andrea Messa 856435
Andrea Tirico 851958

OBIETTIVI E TECNOLOGIE UTILIZZATE

L'obiettivo del progetto nel verificare la documentazione di MongoDB per quanto riguarda le transazioni e la verifica della gestione dei dati in caso di spegnimento di un nodo.

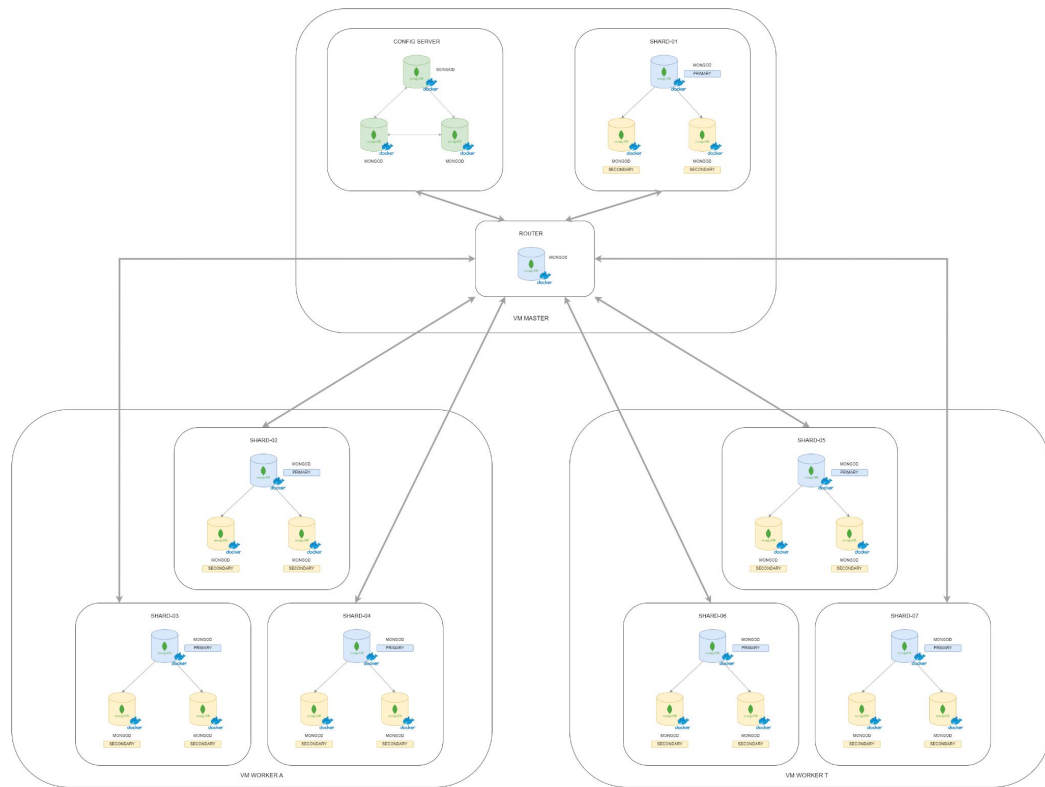

Per svolgere il progetto sono state utilizzate le seguenti tecnologie:

- Docker
- MongoDB
- Mongo Compass
- Visual Studio Code
- Azure Virtual Machine
- Python

ARCHITETTURA

Per il progetto è stata utilizzata un'architettura di sharding ovvero un'architettura di database distribuita che consente di suddividere i dati tra più server o nodi, nei quali ci possono essere uno o più shard.

Nel nostro caso sono stati distribuiti su 3 Virtual Machine: 7 shard, 1 router e 1 config server.

FILE YAML

Nel file YAML si possono avere le seguenti etichette:

- Image
- Container-Name
- Command
- Volumes
- Ports
- Deploy
 - Placement
 - Constraints
- Networks

```
## Config Servers
configsvr01:
  image: mongo:latest
  container_name: mongo-config-01
  command: mongod --port 27017 --configsvr --replset rs-config-server
  volumes:
    - ./scripts:/scripts
  ports:
    - 27118:27017
  deploy:
    placement:
      constraints:
        - node.hostname == master
  networks:
    - net_overlay

configsvr02:
  image: mongo:latest
  container_name: mongo-config-02
  command: mongod --port 27017 --configsvr --replset rs-config-server
  volumes:
    - ./scripts:/scripts
  ports:
    - 27119:27017
  deploy:
    placement:
      constraints:
        - node.hostname == master
  networks:
    - net_overlay

configsvr03:
  image: mongo:latest
  container_name: mongo-config-03
  command: mongod --port 27017 --configsvr --replset rs-config-server
  volumes:
    - ./scripts:/scripts
  ports:
    - 27120:27017
  deploy:
    placement:
      constraints:
        - node.hostname == master
  networks:
    - net_overlay
```

CREAZIONE NETWORK

Per la creazione network ci siamo affidati a una rete overlay. Quest'ultima è una rete virtuale che consente alle diverse istanze distribuite di Docker di comunicare tra loro. Vi sono diversi passaggi da eseguire per creare una network overlay in Docker:

1. Viene configurata un'infrastruttura di rete sottostante che supporti l'overlay, per fare ciò verrà utilizzato Docker Swarm che è un servizio di orchestrazione dei container nativo di docker, il quale permette di avere un'architettura scalabile per gestire i container distribuiti su più host;

```
studente@master:~/Desktop/project_mongo/doc_mongo/project_mongoDB$ docker node ls
```

ID	HOSTNAME	STATUS	AVAILABILITY	MANAGER STATUS	ENGINE VERSION
d8mif3gbcauz70341hv891ci *	master	Ready	Active	Leader	19.03.13
n7pixew0jr7qzkz0frz4ywr9q	workerA	Ready	Active		19.03.13
nfwdk1e652akr5t4z9yq1ftlj	workerT	Ready	Active		19.03.13

2. In seguito viene creata la rete overlay con il comando: *docker network create --driver overlay my-overlay-network*

CREAZIONE NETWORK

- Viene letto il file YAML per determinare i servizi, le configurazioni e le dipendenze specificate e distribuire i nodi sugli host che appartengono alla rete overlay.

```
● studente@master:~/Desktop/project_mongo/doc_mongo/project_mongoDB$ docker stack ps app
```

DISTRIBUZIONE DEI DATI

La procedura utilizzata per distribuire in modo omogeneo il database su ogni shard che compone l'architettura è la seguente:

1. Il primo passo che si effettua è abilitare lo sharding del database;
2. Come secondo step verrà abilitata la collezione che fa parte del database e indicata la shard key;
3. Il passo successivo è quello di caricare il database dentro l'infrastruttura effettuando la mongoimport direttamente dal terminale del router.

```
import json
import random
```

```
example = {
    "id": 1,
    "name": "Pippo",
    "surname": "Pluto",
    "date_of_birth": "18/03/2000",
    "bank": "UniCredit",
    "balance": "10000"
}
```

```
list_name = ['Sofia', 'Matteo', 'Giuseppe', 'Isabella', 'Federico', 'Giulia', 'Carlo', 'Veronica', '
list_surname = ['Rossi', 'Bianchi', 'Russo', 'Esposito', 'Ricci', 'Ferrari', 'Rizzo', 'Romano', 'Con
italian_banks = [
    "Intesa Sanpaolo",
    "UniCredit",
    "Banco BPM",
    "Monte dei Paschi di Siena",
    "UBI Banca",
    "Banca Nazionale del Lavoro",
    "Banca Generali",
    "Mediobanca",
    "Cassa Depositi e Prestiti",
    "Banca Popolare di Sondrio"
]
```

```
banks = []
type(banks)
```

```
list
```

```
for i in range(1, 1001):
    item = example.copy()

    rand_name = random.randint(0, 99)
    rand_year = random.randint(1960, 2004)
    rand_month = random.randint(1, 12)
    rand_day = random.randint(1, 31)
    rand_banca = random.randint(0,9)
    rand_balance = random.randint(1000, 1000000)

    item["id"] = i
    item["name"] = list_name[rand_name]
    item["surname"] = list_surname[rand_name]
    item["date_of_birth"] = f"{rand_day}/{rand_month}/{rand_year}"
    item["bank"] = italian_banks[rand_banca]
    item["balance"] = rand_balance

    banks.append(item)
```

```
with open("banks.json", "w") as outfile:
    json.dump(banks, outfile)
```

```
example
```

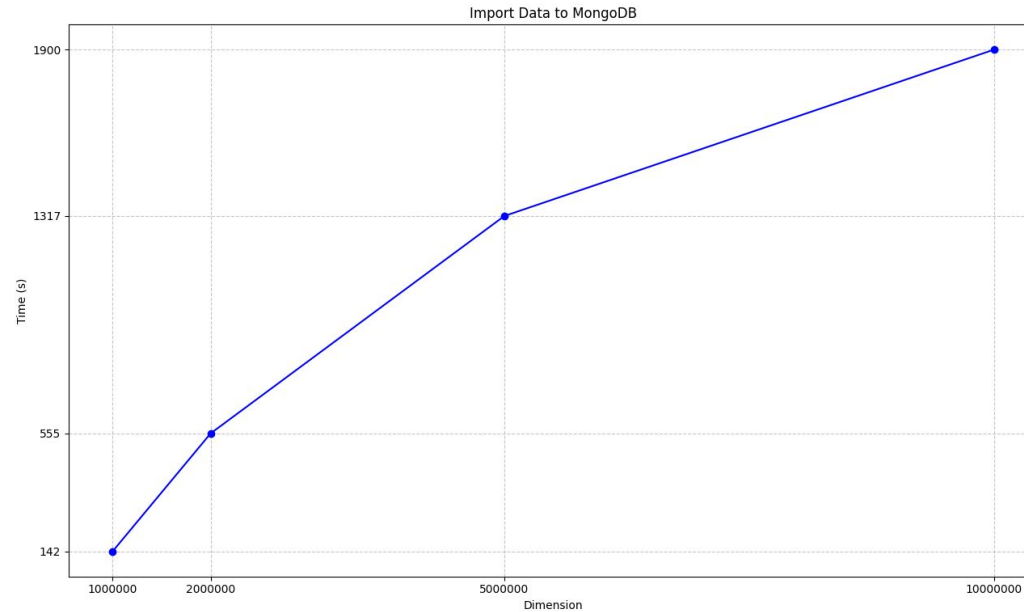

```
{'id': 1,

CONCLUSIONI

Si può dedurre:

- Più dati si inseriscono, più i tempi si riducono in maniera proporzionale
- Le transazioni sono molto stringenti
- Lo spegnimento di nodi restituisce risultati differenti in base a come si impostano le Concern
